

The Pop Bottle Magnetometer - Example Data

Authors: Kira Lee, University of Tasmania

Two examples of pop bottle magnetometer plots and comparisons to geomagnetic observatory declination data are provided below. Additional information and interpretation of the geomagnetic storm conditions during the recording period are also included.

In both examples, the pop bottle magnetometer was set up and run in the Physics Building at the University of Tasmania, Hobart. Timelapse videos from the recording periods can be found here: [The Pop Bottle Magnetometer: Example Timelapses & Data](#)

Note that the room where the pop bottle magnetometer was placed was not perfectly undisturbed and temperature was not controlled. Both factors will have created unwanted noise in the data sets.

Example 1: 13 – 19/05/2026

A **moderate geomagnetic storm** event was recorded during the observation period (13/05/2026 - 19/05/2026).

The pop bottle magnetometer data shows a clear disturbance on 16/05/2026 at approximately 08:30 Hobart time (22:30 UT on 15/05/2026). This is visible as a spike in the reflected laser spot position reaching 19.4 cm, corresponding to an estimated deflection of $\sim 1^\circ$ in the magnetic field (**Figure 1**).

This disturbance is consistent with a geomagnetic storm event, as the [Kp index](#) reached 6.0 at 21:00 UT on 15/05/2026 (Matzka, 2021). A Kp value of 6 corresponds to a moderate (G2) storm on the [NOAA space weather scale](#).

A disturbance in the Hobart Geomagnetic Observatory geomagnetic declination data is consistent with the pop bottle data (**Figure 2**). A spike is clearly visible in the data late on 15/05/2026 (UT) which aligns closely in timing with the disturbance in the pop bottle magnetometer data.

This agreement strongly suggests that both instruments recorded the same moderate geomagnetic storm event.

Figure 1: Pop bottle magnetometer data 13-19/05/2026. Hobart time (UT+10). Degrees of geomagnetic deflection was calculated according to NASA (2015). Reference laser spot position was 15 cm.

Figure 2: Hobart Geomagnetic Observatory geomagnetic declination data 13-19/05/2026. UT time. (Space Weather Services (Bureau of Meteorology), World Data Centre for Geomagnetism)

Example 2: 20 – 27/05/2026

Geomagnetic activity levels remained quiet during this observation period (20/05/2026 - 27/05/2026).

No geomagnetic storms occurred during this week as [Kp values](#) remained below 5 throughout (Matzka, 2021). According to [NOAA space weather scales](#), Kp must reach a value of 5 for a minor (G1) storm event to be classified.

This quiet activity is reflected by the small ($< 0.3^\circ$) degrees of deflection and relatively stationary reflected laser spot position (< 1.5 cm displacement) (**Figure 3**). Similarly, the Hobart Geomagnetic Observatory declination data (**Figure 4**) lacks any significant disturbances during this period, which is consistent with the pop bottle magnetometer observations.

Figure 3: Pop bottle magnetometer data 20-27/05/2026. Hobart time (UT+10). Degrees of geomagnetic deflection was calculated according to NASA (2015). Reference laser spot position was 14.7 cm.

Figure 4: Hobart Geomagnetic Observatory geomagnetic declination data 20-27/05/2026. UT time. (Space Weather Services (Bureau of Meteorology), World Data Centre for Geomagnetism)
